Abstract
A wide range of researches are carried out in this field for denoising, enhancement and more. Besides the other, stress management is important to identify the spot in which the stress has to be made in speech. In this paper, in order to provide proper speech practice for the abnormal child (mentally retarded (MR) child), their speech is analyzed. Initially, the normal and abnormal children speech is obtained with the same set of words. As an initial process, the Mel Frequency Cepstrum Coefficients (MFCC) is extracted from both words and the Principal Component Analysis (PCA) is applied to reduce the dimensionality of the words. From the dimensionality reduced words, the parameters are obtained and then these parameters are utilized to train using Support Vector Machines (SVM) for classification. After identifying the acute word (abnormal word), through the thresholding operation and then FFT is computed for the acute word and these parameters made use of the Fuzzy Inference system (FIS) for blemishing the acute spot in which the aberration is occurred in the world where the speech practice is required for the abnormal child which helps speech pathologist.

Keywords: Speech signal, Stress, Mel Frequency Cepstrum Coefficients (MFCC), Principal Component Analysis (PCA), Support Vector Machines (SVM), Fuzzy Inference system (FIS)

1. Introduction
Effective determination of quantitative speech disability remains one of the challenges in medical profession. Mental Retardation/Intellectual Disability (MR/ID) has been particularly challenging as the term mentally retarded carries significant social and emotional stigma. Developmental delay is often used inappropriately as synonymous with MR/ID. Speech synthesis among the disabled children is the first step for making speech corrective tool kit.

Generally, the speech recognition has two stages: feature extraction and classification (Bharathi and Shanthi, 2011). This work is very useful for the speech practitioners in the way, in which position they have to improve the speech of the abnormal person. Initially, the samples of the normal as well as the abnormal person’s speech have been obtained and with the aid of these samples, the further process has to be carried out. Initially, the MFCC of both the speeches are extracted and the PCA is applied to the MFCC to reduce the dimensionality of the speeches. After that the parameters are extracted from this MFCC of both speeches and then these speeches are inputted to generate the ANN.

The abnormal and normal features are used to train the network. Subsequently, the acute word is identified through the thresholding operation and then FFT of the acute word is identified. From the FFT of the acute word, number of maximum peaks and their amplitude is identified. The amplitude and number of peaks are inputted to the Fuzzy Inference System for the optimization process to identify the position in which the stress has to given.

1.1 MFCC
Feature extraction is a key issue for efficient speaker recognition. Additionally, a reduced feature set would allow more robust estimates of the model parameters, and less computational resources would be required. Best features are those that help to discriminate among speakers. A small amount of data is enough to estimate good models. State-of-the-art systems use the same short-term spectrum features (Mel-Frequency Cepstral Coefficients, MFCC) for speech and speaker recognition, because MFCC convey not only the frequency distribution identifying sounds, but also the glottal source and the vocal tract shape and length, which are speaker specific features. Additionally, it has been shown that dynamic information improves significantly the performance of recognizers, so MFCC are commonly used as features (Bharathi and Shanthi, 2011).

1.2 Principal Component Analysis (PCA)
PCA is an technique of multivariate statistical analysis (Bharathi and Shanthi, 2011), consists of computing the eigenvectors of the D*D covariance matrix X, then sorting them according to the corresponding eigenvalues, in descending order, and finally building the projection matrix A (called Karhunen-Loeve Transform, KLT) with the largest K eigenvectors (i.e. the K directions of
Indian Journal of Innovations and Developments

The speech samples are extracted from the normal and pathological subjects with the aid of the audio synthesizer. Let AB and N be the abnormal children, normal children speech datasets respectively and from these datasets the MFCC feature is extracted. [4]

MFCC’s are based on the known variation of the human ear’s critical bandwidths with frequency. The MFCC technique makes use of two types of filter, namely, linearly spaced filters and logarithmically spaced filters. The MFCC features are obtained from the normal as well as abnormal datasets which is referred as N and AB. PCA is used abundantly in all forms of analysis - from neuroscience to computer graphics - because it is a simple, non-parametric method of extracting relevant information from confusing data sets. With minimal additional effort PCA provides a roadmap for how to reduce a complex data set to a lower dimen-
sion to reveal the sometimes hidden, simplified dynamics that often underlie it. PCA was used to reduce the dimensionality. After this process completed, the following parameters are obtained from the MFCC featured vectors $N_{M_a,ABM_b}^M$. The parameters are mean, standard deviation, maximum amplitude value and its id, minimum amplitude value and its id, MFCC length are extracted for the MFCC featured word and as well as for the original word also extracted and hence for each word we have 14 inputs (Bharathi and Shanthi, 2012).

### 2.3 Classification through Support Vector Machines (SVMs)

SVM is

- An optimally defined surface
- Linear or nonlinear in the input space
- Linear in a higher dimensional feature space
- Implicitly defined by a kernel function $K(A,B) \rightarrow C$

The very best algorithms today are typically quadratic and required multiple scans of the data (Bharathi and Shanthi, 2012).

**Figure 1: Data Flow for Feature Extraction**

2. Extract MFCC feature for normal & abnormal word
3. Apply PCA on MFCC
4. Obtain 7 MFCC features of words
5. Obtain 7 normal features of words
6. Both features (14) combined as feature vector
7. For Classification using SVM
8. For Classification using SVM

**Figure 2: Linear separation of the datapoints into two classes**

Let us consider a linear binary classification task, as depicted in figure 1 & 2, with m data points in the n dimensional input space $R^n$, represented by the mxn matrix $A$, having corresponding labels $\pm 1$, denoted by the mxm diagonal matrix $D$ of $\pm 1$. For this problem, the SVMs try to find the best separating plane, i.e. furthest from both class $+1$ and class $-1$. It can simply maximize the distance or margin between the support planes for each class ($xtw = b+1$ for class $+1$, $xtw = b-1$ for class $-1$). The margin between these supporting planes is $2/||w||$. Any point falling on the wrong side of its supporting plane is considered to be an error. Therefore, the SVMs have to simultaneously maximize the margin and minimize the error. Both the words of normal and pathological subjects are inputted to the SVM to be trained and to identify the abnormal word. The 14 features extracted for each word is given as input to SVM. Here we combine these 14 inputs into a single vector for training SVM i.e. $IP$. The SVM is utilized to train this $IP$ with the intention of recognizing the abnormal words.

### 2.4 Proposed Technique for identifying abnormal spot

#### 2.4.1 Fuzzy Inference system (FIS) to spot the aberration spot

The fuzzy inference system is comprised of 3 phases that are Fuzzification, Rules Evaluation and Defuzzification. Fuzzy inference is the process of creating a mapping from a given input to an output by means of a fuzzy logic. Then, the mapping provides a basis from which decisions can be made, or patterns discerned. The process of fuzzy inference involves Membership Functions, Logical Operations, and If-Then Rules. In this FIS, we utilize the peaks of the abnormal words in order to identify the aberration spot. These peak values are utilized for the fuzzy system (Figure 3).
2.4.2 Fuzzification

In the fuzzification process, the crispy quantities are changed into fuzzy in order to accomplish the tasks. In our proposed method, the peaks of each abnormal word are utilized for identifying the apt aberration spot.

2.4.3 Fuzzy Rules generation

Subsequent to the fuzzification, the fuzzy rules are generated based on the fuzzy values of each word. Generally, fuzzy rules are in the form of “IF A THEN B”. The IF-part of the rule is called as antecedent, and the THEN-part of the rule is called as the conclusion. The generated fuzzy rules will train the FIS with the output values based on the threshold.

2.4.4 Defuzzification

In the defuzzification process, the fuzzy set is utilized as an input and output is obtained as a single number. To the extent that fuzziness supports the rule evaluation during the intermediate steps, and the final output for every variable is usually a single number.

3. Experimental Setup

3.1 The speech database

In this with the aid of the Free Audio Editor we generate the dataset with the normal and abnormal female children within the age limit 6-10 yrs. For normal data 2 female children are utilized and for abnormal data a female child is utilized for the system and their normal frequency range is from 20 - 4 kHz. The proposed technique is tested with the database of 100 words with two normal children and an abnormal child each of same scripts (Bharathi and Shanthi, 2011).

3.2 Classification using SVM

Here we detail the SVM classification for the abnormality of words. The following equation is the SVMs’ objective function which may identifies the support vector for the classification.

\[
\mathbf{R} \ s = \sum_{i} \omega_i \cdot K (s_i, lpr) + b_i
\]

Here
\[ s_i = \text{support vectors} \]
\[ \omega_i = \text{weight} \]
\[ b = \text{bias} \]
\[ lpr = \text{vectors for classification} \]
\[ kr = \text{kernel function} \]

The equation (3) is the objective function utilizes an optimization method to identify the support vectors, weights and bias for classifying the vector \( IP \) where \( kr \) is a kernel function. In the case of a linear kernel, \( kr \) is the dot product (Figure 4).
3.2.1 Algorithm:

Step 1: Check whether the “Res” is greater than Threshold value
Step 2: If “Res” is greater than or equal to the Threshold value then:
   The word is considered as “Normal”
Step 3: Else:
   The word is considered as “Abnormal”
The above algorithm indicates that if the value of the variable “Res” greater than the threshold value then the class belongs to the normal category else it may belong to the abnormal category. SVM contains error also the error minimization function is as follows

\[
\arg \min P \sum_{x=1}^{n} \nu_x + 0.5 \lambda^T \lambda
\]

with the following constraints,

\[
\lambda^T k (\lambda^T k (Ipr_x) + c1) \geq 1 - \nu_x
\]

and

\[
\nu_x \geq 0
\]

In Eq. (4), \(p\) is the penalty constant, \(\nu\) handles the data and \(\lambda\) - matrix of coefficients. According to the Eq. (5) and (6), \(k\) is the class label of the \(x^{th}\) dataset, \(c1\) is a constant and \(k\) is the kernel which transforms the input data to the feature space. Hence, by minimizing the error function, the SVM learns the training dataset \(Ipr\) well and so that it can classify the vector that is similar to the training set. After the errors are minimized we obtain the abnormal words separately. [Excite] (Figure 7)

3.3 Identifying the acute spot of abnormality

In this section, the spot in which the speech practice is required is found. Prior to this process, the identified abnormal word is stored in the vector $A_v$ comprised of abnormal words. With the aid of the thresholding operation the acute word is extracted and stored. In this module, the identified abnormal speech sample is utilized to identify the position in abnormal speech, to be trained by the speech practitioners. For this, the abnormal speech is identified and the FFT is computed for the abnormal speech. The sudden changes in frequency can be seen in FFT by maximum peaks. The numbers of maximum peaks are analyzed with its amplitude using FFT. This each peak is considered as a gene. The result of FFT is analyzed and number of peaks are approximately chosen as 20. The amplitude and its value in the FFT obtained are the parameters utilized by the FIS to spot the acute location in the speech for improvisation by speech pathologist.

3.3.1 Fuzzy Inference system (FIS) to spot the aberration spot

The fuzzy inference system is comprised of 3 phases that are Fuzzification, Rules Evaluation and Defuzzification. The process of fuzzy inference involves Membership Functions, Logical Operations, and If-Then Rules. In this FIS, we utilize the peaks of the abnormal words in order to identify the aberration spot. These peak values are utilized for the fuzzy system (Figure 8).

3.3.2 Fuzzification

In the fuzzification process, the crispy quantities are changed into fuzzy in order to accomplish the tasks. In our proposed method, the peaks of each abnormal word are utilized for identifying the apt aberration spot. Here the following equation indicates that the general peaks of an abnormal word.

$$H = \{p_1, p_2, p_3 \ldots p_{N_v-1}\}$$

For the fuzzification process we utilize the normal words’ peak value in order to identify the divergence of both peaks if the peak may have high divergence when compared to the threshold then it may marked in the signal of that abnormal word. Compare the peaks of Normal words’ and abnormal words’ peak values i.e. $\phi$

If $\phi$ value is greater than the threshold then
The amp value is selected
Else the amplitude value of the abnormal Word is deselected.

3.3.3 Defuzzification

In the defuzzification process, the fuzzy set is utilized as an input and output is obtained as a single number. To the extent that fuzziness supports the rule evaluation during the intermediate steps, and the final output for every variable is usually a single number. Here the single number value indicates either the amplitude is selected to mark or unmark it to indicate the aberration spot. The FIS is trained with the fuzzy rules and the testing process is performed by the number of testing words.

4. Experimental Results

4.1 Feature Extraction

Initially, the words are extracted from the both normal and abnormal children and then the MFCC feature has been extracted
from it. Subsequently, the PCA is applied to reduce the dimensionality of the words. Few speech samples which are sent as input to MFCC Feature Extraction (Bharathi and Shanthi, 2012).

4.2 Classification using SVM

Subsequently, for MFCC features the PCA is applied to reduce the dimensionality of the words and then they are inputted to the SVM to identify the abnormal and the normal word. The result is shown as,

4.3 Finding spot using FIS

In this work, the proposed technique is tested with the database of 100 words with normal children 2 and an abnormal child data. Then the acute spot of aberration for the abnormal words is identified using FIS.

5. Conclusions and Future work

The proposed system was implemented in the working platform of MATLAB (version 7.11). In this with the aid of the Free Audio Editor, the dataset with the normal and abnormal female children within the age limit 6-10 yrs are generated. For 100 normal data (words) 2 female children were utilized each and for 100 abnormal data, a female child was utilized for the system and their normal frequency range is from 20 – 4 kHz. The speech input is recorded at a sampling rate of 44.1 kHz. This work is an effective system to identify the acute spot in abnormal word (MR Child’s speech), where the speech has to be improved. Such that this information helps the Speech pathologist to give more practice in that region of word for that child directly. For this initially the MFCC is obtained from both the normal and abnormal words and PCA dimensionality reduction is done. Then classification of normal and abnormal words is done using SVM. After that, acute Spotting aberration in speech of pathological subject is done using FFT and FIS. The result of this work was discussed with outputs.
